Linear State-Space Control Systems

In control engineering, a state-space representation is a mathematical model of a physical system as a set of input, output and state variables related by first-order differential equations or difference equations. State variables are variables whose values evolve over time in a way that depends on the values they have at any given time and on the externally imposed values of input variables.

The state space model of Linear Time-Invariant (LTI) system can be represented as, $\dot{X} = AX + BU$. $Y = CX + DU$. The first and the second equations are known as state equation and output equation respectively. Where, X and \dot{X} are the state vector and the

differential state vector respectively. U and Y are input vector and output vector respectively.

For a SISO LTI system, the state-space form is given below: (1) (2) where is an n by 1 vector representing the system's state variables, is a scalar representing the input, and is a scalar representing the output.

Introduction: State-Space Methods for Controller Design

- Most general continuous-time linear dynamical system has form $\dot{x}(t) = A(t)x(t) + B(t)u(t)$ $y(t) = C(t)x(t) + D(t)u(t)$ where:
 - $t \in \mathbb{R}$ denotes time
 - $x(t) \in \mathbb{R}^n$ is the state (vector)
 - $u(t) \in \mathbb{R}^m$ is the input or control
 - $y(t) \in \mathbb{R}^p$ is the output
 - $A(t) \in \mathbb{R}^{n \times n}$ is the dynamics matrix
 - $B(t) \in \mathbb{R}^{n \times m}$ is the input matrix

State space analysis. State space analysis is an excellent method for the design and analysis of control systems. The conventional and old method for the design and analysis of control systems is the transfer function method. The transfer function method for design and analysis had many drawbacks. Advantages of state variable analysis.

CONTROL SYSTEM ENGINEERING-II (3-1-0)

An nth order linear physical system can be represented using a state space approach as a single first order matrix differential equation: The first equation is called the state equation and it has a first order derivative of the state variable(s) on the left, and the state

State Space Representations of Linear Physical Systems

A state-space model is a mathematical representation of a physical system as a set of input, output, and state variables related by first-order differential equations. The state variables define the values of the output variables. The ss model object can represent SISO or MIMO state-space models in continuous time or discrete time.

The state of a linear, time-invariant physical discrete-time system is assumed to satisfy $x(k+1) = Ax(k) + Bu(k)$ $y(k) = Cx(k) + Du(k)$

Linear control Systems described by the state-space equations are named linear systems, because the matrix arithmetic imposes a linear relationship between controls, states and outputs. Every real-world machine and device is non-linear. Even a water heater is not linear (the definition of calorie is strictly true for water at 19.5C only).

The "sense-and-correct" nature of feedback controllers make them an appealing choice for systems whose actuators, or environments, are highly variable. If the system also requires high performance (e.g. an industrial robot, a car, or an aircraft), the usual approach is to use a state-space feedback controller derived from a physics-based model.

The state-space equations can be solved for time-variant systems, but the solution is significantly more complicated than the time-invariant case. Our time-variant state equation is given as follows: $\dot{x} = Ax + Bu$ We can say that the general solution to time-variant state-equation is defined as:
