Orbital hybridization . The observation of molecules in the various electronic shapes shown above is, at first blush, in conflict with our picture of atomic orbitals. For an atom such as oxygen, we know that the 2s orbital is spherical, and that the 2p<sub>x</sub>, 2p<sub>y</sub>, and 2p<sub>z</sub> orbitals are dumbbell-shaped and point along the Cartesian axes. The water molecule contains two hydrogen atoms bound to oxygen not at a 90° angle, but at an angle of 104.5°.

atomic orbitals into new hybrid orbitals suitable for the pairing of electrons to form chemical bonds in valence bond theory. Hybrid orbitals are very useful in the explanation of molecular geometry and atomic bonding properties and are symmetrically disposed in space. Although sometimes taught together with the valence shell electron-pair repulsion theory, valence bond and hybridisation are in fact not related to the VSEPR model.

### **Orbital hybridisation - Wikipedia**

In order to explain this observation, valence bond theory relies on a concept called orbital hybridization. In this picture, the four valence orbitals of the carbon (one 2 s and three 2 p orbitals) combine mathematically (remember: orbitals are described by equations) to form four equivalent hybrid orbitals, which are named  $sp^3$  orbitals because they are formed from mixing one s and three p orbitals.

The hybridization of an s orbital (blue) and three p orbitals (red) produces four equivalent  $sp^3$  hybridized orbitals (purple) oriented at  $109.5^\circ$  with respect to each other. A molecule of methane,  $CH_4$ , consists of a carbon atom surrounded by four hydrogen atoms at the corners of a tetrahedron.

Hybridization occurs when we combine two atomic orbitals to form hybrid orbitals. Hybridization helps us overcome the problem of how molecules bond with one another. Bonding solely with s and p orbitals would not necessarily yield the best spatial orientation for our compound.

This type of hybridization involves the mixing of one 's' orbital and one 'p' orbital of equal energy to give a new hybrid orbital known as an sp hybridized orbital. sp hybridization is also called diagonal hybridization. Each sp hybridized orbital has an equal amount of s and p character, i.e., 50% s and p character.

Salient Features of Hybridisation Type of hybridisation indicates the geometry of molecules. The hybridised orbitals are always equivalent in energy and shape. The bond formed by hybrid orbitals is much more stable than the bond formed by the pure atomic orbitals.

## **Hybridization - Organicmystery.com**

Hybridization theory is a technique we use to describe the orbital structure of a molecule. Hybridization is the formation of hybrid orbitals by mixing two or more atomic orbitals. The orientation of these orbitals determines the geometry of the molecule. It is an expansion of the valence bond theory.
