The engine shown is a double-acting steam engine because the valve allows

high-pressure steam to act alternately on both faces of the piston. The following animation shows the engine in action. You can see that the slide valve is in charge of letting the high-pressure steam into either side of the cylinder.

A steam engine is a heat engine that performs mechanical work using steam as its working fluid. The steam engine uses the force produced by steam pressure to push a piston back and forth inside a cylinder. This pushing force is transformed, by a connecting rod and flywheel, into rotational force for work. The term "steam engine" is

Steam is first admitted from the boiler to the cylinder. The pump end of the beam is heavier than the piston so the piston rises and the pump falls during this action. When the piston reaches the top, water is sprayed into the cylinder to cool the steam and hence form a vacuum in the cylinder.

A steam engine is a machine that burns coal to release the heat energy it contains—so it's an example of what we call a heat engine. It's a bit like a giant kettle sitting on top of a coal fire. The heat from the fire boils the water in the kettle and turns it into steam.
